

Lecture 3: Planning by Dynamic Programming

1. Introduction

What is Dynamic Programming?

Dynamic sequential or temporal component to the problem

Programming optimising a "program", i.e. a policy

- c.f. linear programming
- A method for solving complex problems
- By breaking them down into subproblems
 - Solve the subproblems
 - Combine solutions to subproblems

Requirements for Dynamic Programming

Dynamic Programming is a very general solution method for problems which have two properties:

- Optimal substructure
 - Principle of optimality applies
 - Optimal solution can be decomposed into subproblems
- Overlapping subproblems
 - Subproblems recur many times
 - Solutions can be cached and reused
- Markov decision processes satisfy both properties
 - Bellman equation gives recursive decomposition
 - Value function stores and reuses solutions

Planning by Dynamic Programming

- Dynamic programming assumes full knowledge of the MDP
- It is used for planning in an MDP
- For prediction:
 - Input: MDP $\langle S, A, P, R, \gamma \rangle$ and policy π
 - or: MRP $\langle S, P^\pi, R^\pi, \gamma \rangle$
 - Output: value function v_π
- Or for control:
 - Input: MDP $\langle S, A, P, R, \gamma \rangle$
 - Output: optimal value function v_*
 - and: optimal policy π_*

Other Applications of Dynamic Programming

Dynamic programming is used to solve many other problems, e.g.

- Scheduling algorithms
- String algorithms (e.g. sequence alignment)
- Graph algorithms (e.g. shortest path algorithms)
- Graphical models (e.g. Viterbi algorithm)
- Bioinformatics (e.g. lattice models)

2. Policy Evaluation

Iterative Policy Evaluation

- Problem: evaluate a given policy π
- Solution: iterative application of Bellman expectation backup
- $v_1 \rightarrow v_2 \rightarrow \dots \rightarrow v_\pi$
- Using synchronous backups,
 - At each iteration $k + 1$
 - For all states $s \in \mathcal{S}$
 - Update $v_{k+1}(s)$ from $v_k(s')$
 - where s' is a successor state of s
- We will discuss asynchronous backups later
- Convergence to v_π will be proven at the end of the lecture

Iterative Policy Evaluation (2)

$$v_{k+1}(s) = \sum_{a \in \mathcal{A}} \pi(a|s) \left(\mathcal{R}_s^a + \gamma \sum_{s' \in \mathcal{S}} \mathcal{P}_{ss'}^a v_k(s') \right)$$
$$\mathbf{v}^{k+1} = \mathcal{R}^\pi + \gamma \mathcal{P}^\pi \mathbf{v}^k$$

Evaluating a Random Policy in the Small Gridworld

- Undiscounted episodic MDP ($\gamma = 1$)
- Nonterminal states $1, \dots, 14$
- One terminal state (shown twice as shaded squares)
- Actions leading out of the grid leave state unchanged
- Reward is -1 until the terminal state is reached
- Agent follows uniform random policy

$$\pi(n|\cdot) = \pi(e|\cdot) = \pi(s|\cdot) = \pi(w|\cdot) = 0.25$$

Iterative Policy Evaluation in Small Gridworld

Iterative Policy Evaluation in Small Gridworld (2)

3. Policy Iteration

How to Improve a Policy

- Given a policy π
 - Evaluation** the policy π
$$v_{\pi}(s) = E[R_{t+1} + \gamma R_{t+2} + \dots | S_t = s]$$
 - Improve** the policy by acting greedily with respect to v_{π}
$$\pi' = greedy(v_{\pi})$$
- In Small Gridworld improved policy was optimal, $\pi' = \pi^*$
- In general, need more iterations of improvement / evaluation
- But this process of **policy iteration** always converges to π^*

Policy Iteration

Policy evaluation Estimate v_π

Iterative policy evaluation

Policy improvement Generate $\pi' \geq \pi$

Greedy policy improvement

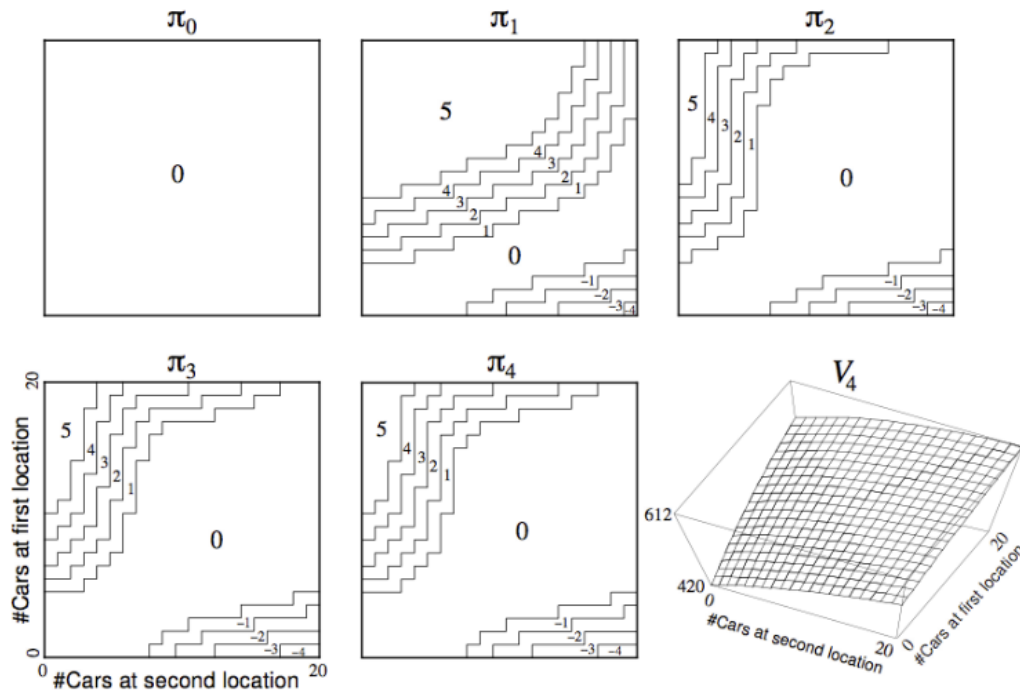

Jack's Car Rental

- States: Two locations, maximum of 20 cars at each
- Actions: Move up to 5 cars between locations overnight
- Reward: \$10 for each car rented (must be available)
- Transitions: Cars returned and requested randomly
 - Poisson distribution, n returns/requests with prob $\frac{\lambda^n}{n!} e^{-\lambda}$
 - 1st location: average requests = 3, average returns = 3
 - 2nd location: average requests = 4, average returns = 2

Policy Iteration in Jack's Car Rental

Policy Improvement

- Consider a deterministic policy, $a = \pi(s)$
- We can improve the policy by acting greedily
 - $\pi'(s) = \arg \max_{a \in A} q_\pi(s, a)$
- This improves the value from any state s over one step,
 - $q_\pi(s, \pi'(s)) = \max_{a \in A} q_\pi(s, a) \geq q_\pi(s, \pi(s)) = v_\pi(s)$
- It therefore improves the value function, $v_{\pi'} \geq v_\pi(s)$
 - $$\begin{aligned} v_\pi(s) &\leq q_\pi(s, \pi'(s)) = E_{\pi'}[R_{t+1} + \gamma v_\pi(S_{t+1}) | S_t = s] \\ &\leq E_{\pi'}[R_{t+1} + \gamma q_\pi(S_{t+1}, \pi'(S_{t+1})) | S_t = s] \\ &\leq E_{\pi'}[R_{t+1} + \gamma R_{t+2} + \gamma^2 q_\pi(S_{t+2}, \pi'(S_{t+2})) | S_t = s] \\ &\leq E_{\pi'}[R_{t+1} + \gamma R_{t+2} + \dots | S_t = s] = v_{\pi'}(s) \end{aligned}$$
- If improvements stop
 - $q_\pi(s, \pi'(s)) = \max_{a \in A} q_\pi(s, a) = q_\pi(s, \pi(s)) = v_\pi(s)$
- Then the Bellman optimality equation has been satisfied
 - $v_\pi(s) = \max_{a \in A} q_\pi(s, a)$
- Therefore $v_\pi(s) = v_*(s)$ for all $s \in S$
- so π is an optimal policy

Extensions to Policy Iteration

Modified Policy Iteration

- Does policy evaluation need to converge to v_π ?
- Or should we introduce a stopping condition
 - e.g. ϵ -convergence of value function

- Or simply stop after k iterations of iterative policy evaluation?
- For example, in the small gridworld $k = 3$ was sufficient to achieve optimal policy
- Why not update policy every iteration? i.e. stop after $k = 1$
 - This is equivalent to value iteration (next section)

Generalised Policy Iteration

Policy evaluation Estimate v_π

Any policy evaluation algorithm

Policy improvement Generate $\pi' \geq \pi$

Any policy improvement algorithm

4. Value Iteration

Value Iteration in MDPs

Principle of Optimality

Any optimal policy can be subdivided into two components:

- An optimal first action A_*
- Followed by an optimal policy from successor state S'

A policy $\pi(a|s)$ achieves the optimal value from state s , $v_\pi(s) = v_*(s)$, if and only if

- For any state s' reachable from s
- π achieves the optimal value from state s' , $v_\pi(s') = v_*(s')$

Deterministic Value Iteration

- If we know the solution to subproblems $v_*(s')$
- Then solution $v_*(s)$ can be found by one-step lookahead

$$\circ \quad v_*(s) \leftarrow \max_{a \in A} R_S^a + \gamma \sum_{s' \in S} P_{ss'}^a v_*(s')$$

- The idea of value iteration is to apply these updates iteratively
- Intuition: start with final rewards and work backwards
- Still works with loopy, stochastic MDPs

Example: Shortest Path

Value Iteration

- Problem: find optimal policy π
- Solution: iterative application of Bellman optimality backup
- $v_1 \rightarrow v_2 \rightarrow \dots \rightarrow v_*$
- Using synchronous backups
 - At each iteration $k + 1$
 - For all states $s \in S$
 - Update $v_{k+1}(s)$ from $v_k(s')$
- Convergence to v_* will be proven later
- Unlike policy iteration, there is no explicit policy
- Intermediate value functions may not correspond to any policy

$$v_{k+1}(s) = \max_{a \in \mathcal{A}} \left(\mathcal{R}_s^a + \gamma \sum_{s' \in \mathcal{S}} \mathcal{P}_{ss'}^a v_k(s') \right)$$

$$\mathbf{v}_{k+1} = \max_{a \in \mathcal{A}} \mathbf{R}^a + \gamma \mathbf{P}^a \mathbf{v}_k$$

Summary of DP Algorithms

Synchronous Dynamic Programming Algorithms

Problem	Bellman Equation	Algorithm
Prediction	Bellman Expectation Equation	Iterative Policy Evaluation
Control	Bellman Expectation Equation + Greedy Policy Improvement	Policy Iteration
Control	Bellman Optimality Equation	Value Iteration

- Algorithms are based on state-value function $v_\pi(s)$ or $v_*(s)$
- Complexity $O(mn^2)$ per iteration, for m actions and n states
- Could also apply to action-value function $q_\pi(s, a)$ or $q_*(s, a)$
- Complexity $O(m^2n^2)$ per iteration

5. Extensions to Dynamic Programming

Asynchronous Dynamic Programming

- DP methods described so far used synchronous backups
- i.e. all states are backed up in parallel
- Asynchronous DP backs up states individually, in any order
- For each selected state, apply the appropriate backup
- Can significantly reduce computation
- Guaranteed to converge if all states continue to be selected

Three simple ideas for asynchronous dynamic programming:

- In-place dynamic programming
- Prioritised sweeping
- Real-time dynamic programming

In-Place Dynamic Programming

- Synchronous value iteration stores two copies of value function

- for all s in S

- $$v_{new}(s) \leftarrow \max_{a \in A} (R_s^a + \gamma \sum_{s' \in S} P_{ss'}^a v_{old}(s'))$$

- $$v_{old} \leftarrow v_{new}$$

- In-place value iteration only stores one copy of value function

- for all s in S

- $$v(s) \leftarrow \max_{a \in A} (R_s^a + \gamma \sum_{s' \in S} P_{ss'}^a v(s'))$$

Prioritised Sweeping

- Use magnitude of Bellman error to guide state selection, e.g.

- $$| \max_{a \in A} (R_s^a + \gamma \sum_{s' \in S} P_{ss'}^a v(s')) - v(s) |$$

- Backup the state with the largest remaining Bellman error
- Update Bellman error of affected states after each backup
- Requires knowledge of reverse dynamics (predecessor states)
- Can be implemented efficiently by maintaining a priority queue

Real-Time Dynamic Programming

- Idea: only states that are relevant to agent
- Use agent's experience to guide the selection of states
- After each time-step S_t, A_t, R_{t+1}
- Backup the state S_t

- $$v(S_t) \leftarrow \max_{a \in A} (R_{S_t}^a + \gamma \sum_{s' \in S} P_{S_t s'}^a v(s'))$$

Full-width and sample backups

Full-Width Backups

- DP uses *full-width* backups
- For each backup (sync or async)
 - Every successor state and action is considered
 - Using knowledge of the MDP transitions and reward function
- DP is effective for medium-sized problems (millions of states)
- For large problems DP suffers Bellman's *curse of dimensionality*
 - Number of states $n = |\mathcal{S}|$ grows exponentially with number of state variables
- Even one backup can be too expensive

Sample Backups

- In subsequent lectures we will consider *sample backups*
- Using sample rewards and sample transitions $\langle S, A, R, S' \rangle$
- Instead of reward function \mathcal{R} and transition dynamics \mathcal{P}
- Advantages:
 - Model-free: no advance knowledge of MDP required
 - Breaks the curse of dimensionality through sampling
 - Cost of backup is constant, independent of $n = |\mathcal{S}|$

Approximate Dynamic Programming

- Approximate the value function
- Using a function approximator $\hat{v}(s, w)$
- Apply dynamic programming to $\hat{v}(\cdot, w)$
- e.g. Fitted Value Iteration repeats at each iteration k ,
 - Sample states $\tilde{S} \subseteq S$
 - For each state $s \in \tilde{S}$, estimate target value using Bellman optimality equation,

$$\tilde{v}_k(s) = \max_{a \in A} (R_s^a + \gamma \sum_{s' \in S} P_{ss'}^a \hat{v}(s', w_k))$$

- Train next value function $\hat{v}(\cdot, w_{k+1})$ using targets $\{< s, \tilde{v}_k(s) >\}$

6. Contraction Mapping

Some Technical Questions

- How do we know that value iteration converges to v_* ?
- Or that iterative policy evaluation converges to v_π ?
- And therefore that policy iteration converges to v_* ?
- Is the solution unique?
- How fast do these algorithms converge?
- These questions are resolved by contraction mapping theorem

Value Function Space

- Consider the vector space V over value functions
- There are $|S|$ dimensions
- Each point in this space fully specifies a value function $v(s)$
- What does a Bellman backup do to points in this space?
- We will show that it brings value functions closer
- And therefore the backups must converge on a unique solution

Value Function ∞ -Norm

- We will measure distance between state-value functions u and v by the ∞ -norm
- i.e. the largest difference between state values,

$$\|u - v\|_\infty = \max_{s \in S} |u(s) - v(s)|$$

Bellman Expectation Backup is a Contraction

- Define the Bellman expectation backup operator T^π ,
- This operator is a γ -contraction, i.e. it makes value functions closer by at least γ ,

$$\begin{aligned} \|T^\pi(u) - T^\pi(v)\|_\infty &= \|(R^\pi + \gamma P^\pi u) - (R^\pi + \gamma P^\pi v)\|_\infty \\ &= \|\gamma P^\pi(u - v)\|_\infty \\ &\leq \|\gamma P^\pi\| \|u - v\|_\infty \\ &\leq \gamma \|u - v\|_\infty \end{aligned}$$

Contraction Mapping Theorem

For any metric space V that is complete (i.e. closed) under an operator $T(v)$, where T is a γ -contraction,

- T converges to a unique fixed point
- At a linear convergence rate of γ

Convergence of Iter. Policy Evaluation and Policy Iteration

- The Bellman expectation operator T^π has a unique fixed point
- v_π is a fixed point of T^π (by Bellman expectation equation)
- By contraction mapping theorem
- Iterative policy evaluation converges on v_π

- Policy iteration converges on v_*

Bellman Optimality Backup is a Contraction

- Define the Bellman optimality backup operator T^* ,
- $$T^*(v) = \max_{a \in A} R^a + \gamma P^a v$$
- This operator is a γ -contraction, i.e. it makes value functions closer by at least γ (similar to previous proof)

- $$\|T^*(u) - T^*(v)\|_\infty \leq \gamma \|u - v\|_\infty$$

Convergence of Value Iteration

- The Bellman optimality operator T^* has a unique fixed point
- v_* is a fixed point of T^* (by Bellman optimality equation)
- By contraction mapping theorem
- Value iteration converges on v_*
